(54) Title: AN INTEGRATED MEDICAL INFORMATION MANAGEMENT AND MEDICAL DEVICE CONTROL SYSTEM AND METHOD (54) Titre: SYSTEME ET PROCEDE INTEGRES DE GESTION DE L'INFORMATION MEDICALE ET DE L'APPAREILLAGE MEDICAL		
(57) Abstract  An integrated medical information management and medical device control system and method are described that <u>links multiple users</u> and multiple medical devices together in a coordinated fashion. The linkage of users and medical devices is accomplished using a bi-directional network and a centralized host system. Users of the system are able to communicate with each other, operate medical devices from remote locations, access information from diverse sources automatically monitor a patent's status.		
(57) Abrégé  Cette invention concerne un système et un procédé intégrés de gestion de l'information médicale et de l'appareillage médical qui permet de relier des utilisateurs et des dispositifs médicaux multiples de façon coordonnée. La liaison entre utilisateurs et dispositifs médicaux se fait au moyen d'un réseau bi-directionnel et d'un système hôte centralisé. Les utilisateurs du système sont en mesure de communiquer entre eux, de télécommander des dispositifs et d'accéder à des informations de provenance diverse pour surveiller l'état d'un patient.

5                   **AN INTEGRATED MEDICAL INFORMATION MANAGEMENT AND  
MEDICAL DEVICE CONTROL SYSTEM AND METHOD**

10                  **FIELD OF THE INVENTION**

15                  The present invention is related to a medical information management and medical device control system that uses a bi-directional network communication system to coordinate multiple data input sources, provides access to the World Wide Web, and communicates with third parties while using medical devices. Specifically, the present invention relates to the use of the Internet and the World Wide Web to receive and store operational parameters of selected medical devices, patient diagnostic data, and other vital medical information from remote sites. Moreover, the present invention can be used to access the World Wide Web, exchange information between consultants and operators and coordinate the functions of medical devices.

20                  **BACKGROUND OF THE INVENTION**

25                  Technology at the dawn of the twenty-first century has reached a complexity level unimaginined just twenty years ago. Nearly every aspect of our daily life has been affected by microprocessors, computers and computer assisted devices. The impact this technology has had on business and society as is especially evident by the Internet's rapid expansion and the increased role computers are playing in the physical and biological sciences. The benefit these technologies have brought to human kind are enormous and are especially apparent in the field of medicine and healthcare.

35                  However, there are also many adverse consequences associated with the recent 20 technology expansion. As the speed and capacity of computer processors increase, software engineers are continually improving their products to keep pace with the hardware. Consequently, new hardware and their related software is becoming increasing complex creating a "technology overload" for the consumer. The average technology user has great difficulty in maximizing the newer computers' potential and much of their capacity remains 40 unrealized. This "technology overload" can be further exacerbated when the software is imbedded in an already complex machine requiring the operator to master both the devices' mechanical aspects and its software-based operating system. Moreover, when more than one 45 of these complex machines are used simultaneously, the complexity level increases exponentially.

5 Medicine is one of the most technically demanding scientific disciplines. Rapid  
advancements in medical technology have provided physicians and patients with life saving  
options that were unavailable five years ago. Moreover, technical advances have significantly  
improved the life quality for millions of persons previously destined to joyless, painful  
10 5 existences. However, the full potential of these recent technical advances remains unrealized,  
limited by the ability of the user to coordinate, interface and operate a diverse assembly of  
complex medical devices and their associated software based operating systems.

15 One of the most significant technical advances of the last one hundred years is the  
development and proliferation of the Internet. The Internet's emergence has provided the  
10 world with convenient access to a plethora of information. Regardless of the subject matter or  
level of detail required, it can be found on the World Wide Web (Web). The popularity and  
20 accessibility of the Internet has resulted in many companies putting new product information  
and technical releases on their Internet home page long before hard copies are available.  
Therefore, in order to remain on the cutting edge of any profession, especially dynamic  
25 15 technical fields like medicine, it is essential to have ready access to the Internet. However, as  
with the "technology explosion" described above, the "information explosion" the Internet has  
facilitated often adds to life's technical complexity rather than simplifying it. Consequently,  
the Internet, like the recent hardware and software advances often remains under utilized.

30 The Internet and recent advances in the medical sciences could be combined  
20 synergistically to help realize the full potential of both technologies. For example, an Internet  
Web site could be used to coordinate the functions of multiple medical devices, facilitate the  
35 rapid exchange of information between medical professions, provide for remote device  
command and control capabilities and collate patient statistics. The greatest difficulty in  
achieving such a synergistic system is the lack of compatibility between various medical  
40 25 devices. Medical devices generally have proprietary operating systems that limit their ability  
to use data generated by other sources. However, using the Internet, communication between  
theses these diverse operating systems and data sources could be established through a medical  
information management and medical device control system that has been designed to  
45 30 interpret, translate and process data from nearly any conceivable source. As a result, a  
seamless interface could be established that would allow the medical device operator to  
instantly access device operating parameters, current patient status data, technical resources  
and personal preferences.

5           Moreover, such a Web site could be used to provide the medical device operator access  
to consultants during the performance of a medical procedure. The consultants would have  
simultaneous access to the same patient statistics and system data that the attending operator  
has. Real time consultations could occur without geographical limitations putting the world's  
10          5 experts at the bedside of every patient in need. Furthermore, the medical device operator could  
access Internet Web sites to obtain up-to-date technical information without leaving the  
patient's side. The patient could be located in the field, an ambulance, an emergency room, a  
coronary care catheter laboratory, or the sterile field of a surgical suite.

15           Yet even further, the device operator could gain access to interactive teaching  
10          information so that the user can become easily educated on the operation and maintenance  
20          device. Also, the device manufacturer could provide updated software and preventative  
maintenance information to the device without having to physically access the device.

25           Consequently, a Web site integrating medical devices, consultants, administrators,  
15          patient vital statistics, and technical facts would greatly assist hospitals and physicians save  
lives, reduce suffering, spare valuable economical resources and advance the education of  
thousands of healthcare practitioners world wide.

#### SUMMARY OF THE INVENTION

30           It is an object of the present invention to provide a medical information management  
and medical device control system that receives, stores, and provides access to important  
20          patient statistics, medical device operational parameters and operator preferences related to  
35          performing medical procedures.

40           It is another object of the present invention to provide a medical information  
management and medical device control system that utilizes a bi-directional network to  
transmit and receive patient statistics, medical device operational parameters and operator  
45          25 preferences related to performing medical procedures.

45           It is still another object of the present invention to provide an Internet Web Site that  
processes and stores patient statistics, clinical data, imaging data, procedural indications,  
medical device operational parameters and operator preferences related to performing medical  
50          50 procedures received from multiple remote locations.

55          30           It is yet another object of the present invention to provide an Internet Web site that can  
coordinate and interface a number of different medical devices simultaneously.

5 It is another object of the present invention to provide an Internet Web site that an operator can access from a remote site and, through the Internet Web site, control and command the medical device.

10 It is yet another object of the present invention to provide an Internet Web site whereby 5 an operator can contact a consultant who, through the Web site of the present invention, has simultaneous access to the same patient vital statistics, clinical data, imaging data, medical 15 device operational parameters and operator preferences related to performing medical procedures available to the operator of the medical device. Further, the scope and particulars 10 of the data transmitted to the consultant can be limited automatically using pre-stored or user defined parameters to protect confidentiality.

20 It is still another object of the present invention to provide an Internet Web site that allows the operator to search the contents of other Internet Web sites while continuing to perform the medical procedure. Further, the operator would be able to simultaneously contact 25 one or more consultants using the Internet, Intranet, telephone or a combination of the 15 communication pathways.

30 It is another object of the present invention to provide an Internet Web site that interfaces with a hospital or other healthcare provider's administrative systems to assist with providing information management and control over medical devices and procedures.

35 The medical information management and medical device control system of the present 20 invention has a bi-directional network to coordinate multiple data input sources, provide access to the World Wide Web ("the Web"), and communicate with third parties while using medical 40 devices. The preferred embodiment of the present invention uses the Internet as the bi-directional network to access the Web. A dedicated Web site that receives, processes, stores and transmits information related to medical procedures is located within the host system. The 45 host system is generally referred to as a server, but may be any computer or other device capable of receiving, processing and transmitting information. The information transmitted and received by the present invention includes, but is not limited to, medical device operational 50 parameters, personal system preferences, technical updates, research articles, patient vital signs, medication schedules, diagnostics, service requirements, laboratory results, patient histories, procedure reports, equipment inventories, imaging date (e.g. x-ray, angiography, magnetic resonance imaging), third party payor information and e-mail (collectively referred to hereinafter as the "information").

5           The information management system of the present invention is composed of at least one remote transmitting appliance for sending information to a Web site and a remote receiving appliance for accepting information from a Web site. In one embodiment of the present invention the remote transmitting appliance is co-located with the remote-receiving appliance.

10          5   In another embodiment of the present invention the remote transmitting appliance is integrated into a device which does not act as a receiving appliance. Third is an independent device that operates in a sterile field environment using a user interface that preserves the sterility of the user, e.g., an infrared device, a touchscreen with a sterile cover.

15                 The Web site of the present invention has a communication interface for receiving 10 information from each remote transmitting appliance and database for processing and storing the information. The Web site of the present invention also has a bi-directional network connecting the remote transmitting appliances, the remote receiving appliances and the Web site together. This bi-directional network facilitates the exchange of information between the Web site, the remote-transmitting appliances and the remote-receiving appliances.

25          15   The bi-directional network of the present invention has at least one remotely located transmitting and receiving appliance. The remote transmitting and receiving appliances of the present invention may have an information display and input means. Non-limiting examples of 30 remotely located transmitting and receiving means of the present invention include computer terminals, devices for monitoring patient status, diagnostic devices, portable electronic devices, 20 telephones, and radio transmitters. Non-limiting examples of information display means include video monitors, light signals, Teletype printouts, Braille printouts, and audible broadcasts. Information input means include, but are not limited to, keyboards, joy sticks, touch sensitive video screens, bar code reader, push buttons, switches, key punch cards, and 35 microphones.

40          25   Another aspect of the present invention permits the operator to share patient statistics, clinical data, imaging data and medical device operating information with a consultant or other individual. For example, an invited consultant can access the Web site via a remote 45 transmitting and receiving means and directly participate in treating a patient or operating the medical device. Using the Web site of the present invention, the consultant can view vital 30 patient statistics including, but not limited to, laboratory data, medications, and video images of diagnostic tests such as angiograms.

50

5        In yet another embodiment of the present invention the bi-directional network can provide access to operation and control of a medical device through a remote transmitting and receiving appliance. In this embodiment, the actual medical procedure, or portions thereof, can be monitored and conducted at a remote site.

10      5        In still another embodiment of the present invention, the medical information and management system can be used to assess potential outcomes of medical procedures based on statistical probabilities. Algorithms stored in databases are combined with patient vital signs to assist the operator in medical procedure selection. Moreover, the same databases can alert an operator in advance of a life-threatening event, or if necessary, abort the procedure 15      automatically.

20      Another embodiment of the present invention is a method of managing medical information and controlling medical devices by providing a World Wide Web site that has a communication interface and a plurality of user accessible databases. The databases include 25      information related to coordinating and operating multiple, diverse medical devices that can be used simultaneously in the treatment or diagnosis of a patient. Additional databases include, 15      but are not limited to, technical information pertaining to the operation and maintenance of a medical device and user profile information including patient statistics, user preferences, 30      available consultants, and algorithms for risk management.

35      The method of the present invention is also used to receive medical information and 20      medical device operating instructions through the communications interface and to store medical information and medical device operating instructions in its databases. Moreover, 35      medical information and medical device operating instructions and other information can be requested by a plurality of users either individually or simultaneously. The medical information, medical device operating instructions and other requested information is then 40      extracted from the databases of the present invention and transmitted to the healthcare worker 25      treating the patient and/or a direct operator of a medical device. As a result, a plurality of medical devices can be coordinated simultaneously using the communication interface and databases of the World Wide Web site in accordance with the teachings of the present 45      invention.

50      30      As a result of the complexity of the present invention, each element and feature is 55      presented separately. However, it is understood that each element would be combined with other, or all, of the elements into an interactive, integrated system designed to maximize the

5 potential of each element, and through synergy, create medical information management and medical device control system that provides benefits greater than the sum of its parts. Furthermore, while the maximum versatility of the present invention will be realized using the Internet as the bi-directional network, it is also possible to create the integrated medical  
10 5 information management and medical device control system of the present invention using an Intranet. In some applications Intranets may be preferred due to the higher level of security and confidentiality that can be maintained. It is also possible to "hard-wire" all of the devices of the present invention together and avoid using telecommunication devices altogether.  
15 However, hard-wired systems are more expensive to install and less versatile than either  
10 Internet or Intranet based systems.

20 Additional objects and advantages of the present invention and methods of construction of same will become readily apparent to those skilled in the art from the following detailed description, wherein only the preferred embodiments are shown and described, simply by way of illustration of the best mode contemplated of carrying out the invention. As will be realized,  
25 15 the invention is capable of modification in various respects, all without departing from the invention. Accordingly, the drawings and description are to be regarded as illustrative in nature, and not as restrictive.

30 **BRIEF DESCRIPTION OF THE DRAWINGS**

A detailed description of the invention is hereafter described by non-limiting examples  
20 with specific reference being made to the drawings in which:

35 FIG. 1 is a block diagram that depicts the basic elements of the integrated medical information management and medical device control system in accordance with a preferred embodiment of the present invention;

40 FIG. 2 is a block diagram that depicts additional elements of the basic integrated  
25 medical information management and medical device control system in accordance with a preferred embodiment of the present invention;

45 FIG. 3 depicts a bi-directional network communication system coordinating the association of multiple remote-transmitting appliances and remote-receiving appliances with the integrated medical information management and medical device control system in  
30 50 accordance with a preferred embodiment of the present invention;

5 FIG. 4 is a block diagram that depicts additional elements of the user profile database in accordance with a preferred embodiment of the present invention;

10 FIG. 5 is a diagram that depicts the interfacing of multiple medical devices and users in accordance with a preferred embodiment of the present invention.

15 FIG. 6 is a block diagram of a parallel data management aspect of an embodiment of the present invention.

20 FIG. 7 is a block diagram of a segment of the parallel data management system as shown in FIG. 6.

#### DETAILED DESCRIPTION OF THE INVENTION

25 The present invention is an integrated medical information management and medical device control system incorporating a bi-directional network that facilitates the exchange of information and relays instructions between at least one transmitting appliance and at least one receiving appliance. Examples are generally described in co-pending provisional application U.S. Serial No. 60/127,436, the contents of which are hereby incorporated by reference. In one 30 embodiment of the present invention the bi-directional network allows a diverse group of medical devices and computer terminals to exchange data between one another and provides their operators with remote command and control capabilities. In another embodiment of the present invention the bi-directional network provides operators with a means to communicate directly with each other and share information with remote transmitting and receiving 35 appliances.

40 In a preferred embodiment of the present invention the integrated medical information management and medical device control system is a World Wide Web site (Web site). The Web site of the present invention is located within a distant computer referred to as the host system, or server. The host system is usually a computer including, but not limited to, UNIX-based windows/DOS systems, NT-based computers, Linux based computers, and Macintosh 45 computers. The preferred bi-directional network of the present invention is the Internet. Hence, the user can be located at any place where there is access to the Internet, including in the sterile field of the operating room or even at a remote location where access is through a cellular telephone. However, it is understood that secure Intranets and hard-wired systems can 50 also be used to provide access to the integrated medical information management and medical device control system of the present invention. Generally speaking, Intranets are more limiting

5       in scope and versatility, and hard wiring is often even more limiting and usually much more  
expensive. Moreover, a private database housed in a computer that is isolated from the Internet  
could substitute for a Web site as the integrated medical information management and medical  
device control system of the present invention. However, such an isolated system would  
10      5 significantly restrict user access and unnecessarily limit the present invention's versatility.  
Therefore, for the remainder of this Description of the Invention, a Web site accessed through  
the Internet is the preferred embodiment.

15             Turning now to FIG. 1, the integrated medical information management and medical  
device control system 9 of the present invention is depicted. A host communications interface  
10 is shown that serves as the first point of contact between the bi-directional network (the  
Internet) and the integrated medical information management and medical device control  
20      10 system (the Web site). The host communications interface 10 translates data, requests, medical  
information and medical device operating instructions (hereinafter referred to collectively as  
"information") received from diverse transmitting appliances into a standardized format. From  
25      15 the host communications interface 10, the standardized information is sent to a database  
management system 12 that coordinates the flow of information to and from the centralized  
database 14. Information extracted from the centralized database 14 is sent back through the  
database management system 12 where it is routed to a remote receiving appliance 16 either  
30      30 directly, or through the host communications interface 10.

20             In one embodiment of the present invention the host communications interface 10 is  
provided with software that recognizes and translates a plurality of machine languages. In  
35      35 another embodiment of the present invention the host communications interface 10 is provided  
with software that recognizes, translates and formats information received from all commonly  
used medical devices. The software required to provide the host communications interface 10  
40      40 of the present invention with universal recognition, translation and formatting capabilities is  
either commercially available, or written for specific applications by persons of ordinary skill  
in the computer programming arts. In another embodiment, there are more than one input  
45      45 interfaces. For example, one interface may receive digital format live video (e.g., using a  
DICOM standard for transmission), another may accept various formats of analog video,  
50      50 another might recognize and translate a plurality of machine languages, and another might  
provide connection with the Internet or Intranet.

FIG.2 depicts another embodiment of the present invention that combines a firewall 20  
55      55 with the host communications interface 10. The firewall 20 provides secure access to the

5 database management system 12 and screens all incoming information for viruses, corrupt  
files,, system intruders and unwanted e-mail solicitations. Additional security functions as  
known to those skilled in the art can also be provided by the firewall 20. Secure access to the  
database management system 12 is achieved by a password system as known to those skilled in  
10 the art. Additional security features will be described below.

15 Incoming information is translated, formatted and passed through the firewall 20 to the  
database management system 12 which is provided with software known in the art for routing  
the information to the proper database, or databases. Databases of the present invention are  
divided into a hierarchical scheme divided into first, second, third and higher order databases.  
20 Examples of first order databases include, but are not limited to, technical information 24,  
technical updates 26, marketing information 28, frequently requested information 30, user  
profiles 32, regulatory updates and advisories 34, investor information 36, and company  
profiles 38. The database hierarchy is established based on the sequence a user uses to initially  
25 access the database. Information contained within all databases is stored on computer readable  
media, such as a hard disk, floppy drive, CD-ROM, or tape and loaded onto the memory 39  
when in use.

30 FIG. 3 depicts a bi-directional network 40 of the present invention coordinating the  
association of multiple remote-transmitting appliances and/or remote-receiving appliances 48,  
50, and 52 with the integrated medical information management and medical device control  
35 system 9. The remote transmitting and receiving appliances 48, 50, 52 of the present invention  
include, but are not limited to, computer terminals, devices for monitoring patient status,  
diagnostic devices, therapeutic devices, portable electronic devices, telephones, radio  
transmitters, imaging devices or any device capable of accommodating a modem, serial or  
parallel data transmissions, such as a RS232 port, network card or similar transmission means  
40 for transmission of electronic data. FIG. 3 also depicts the bi-directional network 40 linking a  
remote Internet server 44 and an online service provider 46 to the integrated medical  
information management and medical device control system 9. Although FIG. 3 depicts a  
45 minimal number of links 54 in order to simplify the drawing, there are essentially an unlimited  
number of links and associations that the bi-directional network can connect to the integrated  
30 medical information management and medical device control system 9 of the present  
invention.

50 The links 54 to the bi-directional network 40 and communications with the integrated  
medical information management and medical device control system 9 can be established using

5 any method known in the art. Non-limiting examples include a Local Area Network, a discreet modem connection using a Serial Line Internet Protocol (SLIP) or a Point-to Point Protocol (PPP), an Integrated Services Digital Network (ISDN) an Asymmetric Digital Subscriber Line (ADSL), or a coaxial television cable.

10 5 Information can be entered into the transmitting appliances using a variety of input means including, but not limited to keyboards, joy sticks, touch sensitive video screens, bar code readers, push buttons, switches, key punch cards, position sensing devices and microphones. In one embodiment of the present invention the information-input means consists of hands free, voice activated systems whereby verbal commands are spoken into a 15 10 microphone that relays the signal to a transmitting appliance having voice translation software. The translated signals may consist of operational instructions for the local medical device, or be sent through the bi-directional network communication system to a remote-receiving 20 25 appliance or to a Web site.

25 15 Similarly, receiving appliances translate incoming information from the Web site of the present invention and provide the translated information to the operator. The receiving 30 35 appliance presents the information to the operator using a variety of display means including, but not limited to video monitors, light signals (e.g., infrared), radio frequency signals, Teletype printouts, Braille printouts, and audible broadcasts. In another embodiment of the present invention telecommunication means and software are associated with the transmitting 40 45 and/or receiving appliances. The telecommunication means allows for immediate verbal communication between the operator and third parties.

35 15 In one embodiment of the present invention a medical service provider (operator) initiates a medical procedure using at least one medical device located in close proximity to a patient. The medical device has a transmitting appliance and a receiving appliance integrated 40 45 25 into its chassis, or may be connected to a stand-alone transmitting and receiving appliance such as, but not limited to, dumb terminals, terminal emulation, WebTV, computer terminals, and network computers. At anytime before, or during the medical procedure, the operator may use the transmitting appliance associated with the medical device to establish a connection with the 50 55 Web site of the present invention using the Internet or other suitable bi-directional network. 30 Once connected to the Internet, and through it the Web site, an authorized user can access any database depicted in FIG. 2 and FIG. 4. Moreover, the Web site of the present invention provides the operator a portal to the World Wide Web that allows access to any publicly available Web site or subscription service to which the operator subscribes.

5           The operator accesses the Web site of the present invention by transmitting the  
Universal Resource Locator (URL) address through the Internet link that is received by the  
host system housing the Web site of the present invention. The Web site of the present  
invention may be organized in any manner known to those in the art including, but not limited  
10          to, a tree structure, a line structure or randomly. Once the connection is established the Web  
site "home page" is transmitted to the receiving appliance. The operator is asked to enter and  
transmit a password or other identifying code that is received and by host communications  
15          interface 10 (FIG. 2) and transmitted to a firewall 20 (FIG. 2). After the operator is identified  
and authenticated he is allowed to transmit medical information and medical device operating  
10          instructions, or select a first order database 24, 26, 28, 30, 32, 34, 36, and 38 depicted in FIG.2.

20           In one embodiment, the device would automatically connect with the Internet when  
activated. The device would connect to a "home page" for a specific service provider and the  
home page would be customized for the specific device user or location using previously  
entered data extracted from the users usage pattern or direct user input of pre-stored data. The  
25          device manufacturer is one example of a service provider.

30           In another embodiment, video and/or audio programs for training, education, or  
entertainment of healthcare staff or patients would be downloaded from the Internet or Intranet.  
The data transmission would be stored in the data management system described herein or  
displayed directly by the device. Both live and stored transmission would allow for direct  
20          interaction with other sites using Internet or Intranet. For example, display of a training video  
shown live or pulled up from data storage would be accompanied by a "live" audio and/or  
35          video link to another site for interaction with the trainer.

40           Turning now to FIG. 4., the operator selects the first order database, user profiles, 32 to  
initiate the medical device interface with the Web site. A secondary security firewall 60 is  
45          encountered that requires the operator to enter a unique personal user identification that allows  
the operator to proceed. Next, the operator selects from any combination of second order user  
profile databases desired including, but not limited to a medical device database 61, a patient  
statistics database 62, and a user preferences database 63. The number of databases that an  
authorized operator may access within the Web site of the present invention is unlimited. Each  
50          time a new database is accessed, it is displayed as a window on the display device of the  
receiving appliance. Programs for managing the Web site that allows the operator to access  
and interface with the databases are known to those skilled in the art and are stored in the  
database management system 12 (FIG1).

5 One particularly valuable function of the Web site of the present invention is in  
assisting the operator with assessing clinical outcome based on a combination of physiological  
and statistical factors. Physiological factors include vital signs being transmitted to the Web  
site while the patient is undergoing the diagnostic or therapeutic procedure and the patients pre-  
10 existing medical condition. The operator selects a therapeutic procedure option from the menu  
of the statistical analysis and risk management database 65 and inputs his selection.  
Physiological factors and patient attributes are extracted by statistical analysis database 65  
15 from the patient statistics database 62 and an algorithm is applied to information to determine  
what outcome is statistically probable.

10 Statistical analysis database 65 also serves as a patient monitor alerting the operator of  
potentially life threatening events. Software is provided to the statistical database 65 that  
20 enables the Web site to anticipate potentially life threatening situations before a human  
operator would notice the threat. This is possible due to the large amount of medical  
information available to the statistical database 65 and the algorithms contained in the  
25 software. In one embodiment of the present invention the Web site can be instructed to  
override medical devices and/or preempt operator commands if continuing the procedure could  
injure the patient.

30 FIG. 5 depicts a non-limiting example of how the present invention can be used to  
interface multiple medical devices and users simultaneously. Patient 70 is situated in close  
20 proximity to medical device 72 and operator 74 that are collectively located within a sterile  
field 76. For the purposes of this example only, medical device 72 is an angiographic injector  
35 system. A non-limiting example of a suitable angiographic injector system is described in  
pending United States Patent Application Serial Number (USPA SN) 08/966,088, the contents  
of which are hereby incorporated by reference. Co-located with angiographic injector 72 is a  
25 fluoroscope 75 that is providing images of the patient's 70 arteries that are visualized on a  
fluorescent screen 76.

40 The fluoroscope 75 is provided with a transmitting appliance that is connected to the bi-  
directional network 40 (FIG. 3) so that the images displayed on the fluorescent screen 76 are  
45 received by the Web site 9 (FIG. 3). The information, including the fluorescent pictures, sent  
30 by the transmitting appliance incorporated into the fluoroscope 75 is recognized by the host  
communications interface 10 (FIG. 2) and firewall 20 (FIG. 2) of the Web site 9 (FIG. 3).  
50 Recognition of the information sent by the fluoroscope and other remote-transmitting  
appliances is accomplished using software incorporated into microprocessor memories

5 associated with each remote-transmitting appliance. Once received and recognized by the Web site 9 (FIG. 3) the images of the patient's 70 arteries are directed by the database management system 12 (FIG.2) to the first order database user profiles 32 (FIG. 4) and stored in the second order database patient statistics database 62 (FIG. 4).

10                 5 An electrocardiograph (EKG) 78, blood oxygen saturation monitor (SAO<sub>2</sub>) 79 and a respirometer 80 are connected to patient 70 and to the bi-directional network 40 (FIG. 3). Connections to the bi-directional network 40 (FIG 3) are accomplished using a transmitting appliance and software as described above for the angiographic injector 72 or by other means known in the art. The electrocardiograph, heart rate, blood pressure, blood oxygen saturation  
15                 10 and respiration data (collectively referred to hereinafter as "vital signs") obtained from patient 70 by the EKG 78, SAO<sub>2</sub> monitor 79 and respirometer 80 are transmitted to the Web site 9 (FIG. 3) of the present invention. The Web site 9 (FIG.3) receives, processes and stores the patient's 70 vital signs as described generally above.

20                 25 The operator 74 stationed by the angiographic injector 72 interfaces with the Web site 9 (FIG.3) of the present invention using a transmitting and receiving appliance either incorporated within the angiographic injector 72 or a stand alone transmitting and receiving appliance such as a personal computer. In the present example, the angiographic injector described in USPA SN 08/966,088 is provided with a personal computer-based microprocessor incorporated into its chassis. After the operator 74 establishes a link with the  
25                 30 Web site of the present invention 9 (FIG.3) as described in detail above, he can access the patient statistics that has been previously stored in the patient statistics database. Additionally,  
30                 35 the operator 74 can also access the data being transmitted to the Web site by the remote transmitting appliances, including, but not limited to the EKG 78, SAO<sub>2</sub> monitor 79 and respirometer 80.

40                 40 Consequently, the operator 74 has immediate and simultaneous access to all relevant information pertaining to the patient and the medical procedure in one place. Merely by opening different windows on his display device the operator can see the current angiograph, the flow rates of angiographic fluids being injected, the volumes of angiographic fluid injected  
45                 45 and remaining in the reservoir, the patient vital signs, and current laboratory data. Other critical data stored at the Web site of the present invention are available to the operator 74.  
50                 50 Moreover, the operator has access to the World Wide Web including any non-restricted Web sites. For example, if the operator wants to obtain a scientific paper from the National Library of Medicine's Web Site, Pub Med, he enters and transmits the appropriate URL

5 (www.ncbi.nlm.org). The search window at the National Library of Medicine opens on his screen permitting a publication search while maintaining immediate access to the patient statistics described above.

10 Furthermore, the operator has access to a select group of medical consultants through

5 the Web site. These consultants are available for immediate, real time consultations. For example, during an angiographic analysis the operator 74 encounters an anatomical structure unfamiliar to him and the attending staff. The operator 74 opens the second order consultants database 64 (FIG. 4) within the user profiles data base 32 (FIG. 4) and requests a consultant 88, or selects from a list of available consultants. The consultant 88 is contacted using  
10 telecommunication devices known in the art and is notified that his or her services are requested. The consultant then connects to the Web site 9 of the present invention using a remote transmitting and receiving appliance 90 as previously described. The consultant 88 has immediate and simultaneous access to the same information the operator 74 is presently using. For example, the consultant 88 sees the same angiograph that the operator is viewing and has  
15 access to the same vital signs and patient history. The consultant may then either offer the operator her opinion, request further information, or using the remote command and control capabilities of the present invention, take over the procedure from her location. At any point during the procedure other parties, including but not limited to additional consultants, students, and colleagues may join and participate in the procedure or discussion. Each additional party  
20 joining the group through the Web site of the present invention would have his or her participation level determined by their password and/or the operator 74.

35 Moreover, additional information can be sent to the Web site of the present invention and added to the patient database at anytime. For example, a laboratory 86 may have either routine or stat laboratory test results that need to be added to the patient history database. As  
40 25 soon as the laboratory results are received and processed by the Web site of the present invention, the operator, consultants and third parties are notified that the laboratory results are available.

45 Another feature of the present invention is the ability to have transmitting and receiving appliances placed at remote locations. For example, remote receiving and transmitting  
50 30 appliances 82 and 84 are situated outside the sterile field 76 in the present example. Remote operator 81 or 83 situated at these remote transmitting and receiving appliances can access the Web site of the present invention and participate in the procedure to any level authorized by their passwords or by the operator 74. In the case of an emergency, or to give the operator 74 a

5 break, remote command and control functions can be assumed by remote operator 81 or 83. The remote operator 81 or 83 has complete control of the medical procedure, all medical devices connected to the Web site 9 (FIG 3) and access to all information available on the Web site 9 (FIG 4) that the remote operator 81 or 83 have authority to access.

10 5 Another feature of the present invention is the operators' 74, 81, 83 ability to access the Web site of the present invention and its contents from any place in the world. Consequently, the pre-established preferences for a particular medical device along with access to consultants and patient histories are immediately available to the operator regardless of his location. This capacity of the present invention allows a medical procedure to be conducted with consistency 15 10 and reliably at diverse locations.

20 In another embodiment of the present invention the Web site has the capacity to interface with a medical device so that the medical device is actually controlled automatically by information and preferences the physician has previously transmitted and stored in the Web site's user profiles database 32 (FIG. 2).

25 15 In another embodiment of the present invention, the first order data base 24, 26, 28, 30, 32, 34, 36, and 38 depicted in FIG. 2 includes a device service and/or modulating database. This database can be used to upgrade the device operating system. In addition, this database 30 can be used to change the modality of the device. For example, the database can be used to change the injector system disclosed in USPA SN 08/966,088 from one used in cardiology to 20 one used in radiology or MRI applications.

35 35 In still another embodiment of the present invention the first order database 24, 26, 28, 30, 32, 34, 36, and 38 depicted in FIG.2 includes a client management database. The client 40 management database contains second order databases that permit client management databases to track supplies, medical procedures and other information related to inventory 25 control and patient billing. The second order databases are unique for each client and confidentiality is maintained by additional firewalls. After a medical procedure is complete, the hospital's inventory is adjusted to reflect the materials used and the patient's account is 45 automatically charged for the procedure, supplies and hospital staff including the attending physician. Consequently, errors in billing and inventory control are minimized resulting in 30 significant cost savings for the hospital or healthcare institution.

5           In another aspect of the invention, it is important to ensure accuracy of the information  
being transmitted to and from the website, particularly such information that pertains to patient  
statistics. One way of ensuring such accuracy is to provide the data to and from the website in  
a parallel manner and then to compare the data for uniformity before permitting further  
10          5 manipulation or access to the data, for example, for the purpose of device control. In one  
embodiment, the website would signal to the user that the data is corrupt if the data does not  
uniform from both parallel paths.

15           A schematic example of the above-described parallel data management is set forth in  
Figure 6. In this embodiment a medical device 600 arranged to interface with two different  
10          5 Large Area Networks (LAN's), 601, 602. Obviously, each LAN can have multiple user  
interfaces 603, 605. Each of the LANS 601, 602 communicate with the website of the  
invention through the Internet 604 through two separate routers, 606, 608 and communication  
ports 610, 612. The website of the invention then conveys the parallel information to two  
20          10 separate remote LANS 622, 624 through two separate routers, 614, 616 and communication  
ports 618, 620. Provided the data from both routes is uniform, the user is then enable to access,  
25          15 view, respond and otherwise manipulate the data.

30           During the transmission of the data through both routes, the data may periodically be  
compared. For example, the comparison can be performed at the source of the data as it is  
30          20 being transmitted to the LANs 601 and 602. It can also be compared at the website of the  
invention. Alternatively or supplementally, it can be compared at the remote user site.

35           Referring to Figure 7, a schematic is provided showing the medical device 600 and its  
associated accessories, namely, a display 700, a touchscreen 702, a keyboard 704 and other  
related interfaces 706 that input into the processor/encoder/decoder device 706. The processor  
706 then sends out the data in parallel form to two different routers 708, 710 to the respective  
40          25 LANs 601, 602 which are also shown in Figure 6.

45           The preceding examples have been provided to aid the reader in understanding the  
present invention and are not intended to limit the scope of the invention. It is understood that  
that there may be many other configurations and means for providing the same service using  
the integrated medical information and management system of the present invention. It is  
30          40 apparent that while a preferred embodiment of the invention has been shown and described,  
various modifications and changes may be made without departing from the true spirit and  
50          50 scope of the invention.

**Claims**

5 What is claimed is:

1. A medical information management and medical device control system comprising:
  - (a) at least one transmitting appliance for sending medical information and medical device operating instructions to a host system through a bi-directional network;
  - (b) at least one receiving appliance for accepting said medical information and said medical device operating instructions from a host system;
  - (c) a host system comprising:
    - (1) a host communications interface for receiving said medical information and said medical device operating instructions from said at least one transmitting appliance and for transmitting said medical information and said medical device operating instructions to said at least one receiving appliance;
    - (2) a database management system,
    - (3) databases for storing said medical information and/or said medical device operating instructions sent by said at least one transmitting appliances and received by said host communications interface;
    - (d) a bi-directional network connected to said at least receiving appliance, to said at least one transmitting appliance and to said host communication interface for communicating said medical information and said medical device operating instructions between said host communication interface, said at least one receiving appliance, and said at least one transmitting appliance.
2. The medical information management and medical device control system of claim 1 wherein said medical information and said medical device operating instructions are selected from the group consisting of medical device operational parameters, personal system preferences, technical updates, research articles, patient vital signs, imaging data, medication schedules, laboratory results, patient histories and e-mail.
3. The medical information management and medical device control system of claim 1 wherein said bi-directional network is an Internet or Intranet.
4. The medical information management and medical device control system of claim 1 wherein said bi-directional network is a hard-wired network.
5. The medical information management and medical device control system of claim 1 wherein said at least one transmitting appliance is selected from the group consisting of

5 computer terminals, devices for monitoring patient status, diagnostic devices, portable electronic devices, telephones, and radio transmitters.

10 6. The medical information management and medical device control system of claim 1 wherein said at least one receiving appliance is selected from the group consisting of computer terminals, devices for monitoring patient status, diagnostic devices, portable electronic devices, and telephones.

15 7. The medical information management and medical device control system of claim 1 wherein said at least one transmitting appliance has an information input means selected from the group consisting of keyboards, mice, trackballs, light pens, joy sticks, touch sensitive video screens, bar code reader, push buttons, switches, key punch cards, position sensor and microphones.

20 8. The medical information management and medical device control system of claim 1 wherein said at least one receiving appliances have an information display means selected from the group consisting of include video monitors, light signals, Teletype, printouts, Braille printouts, and audible broadcasts.

25 9. The medical information management and control means of claim 6 wherein said devices for monitoring patient status are selected from the group consisting of an electrocardiograph, a blood oxygen saturation monitor, x-ray imaging, magnetic resonance imaging, magnetic resonance spectroscopy, ultrasound imaging and a respirometer.

30 35 10. The medical information management and control means of claim 1 wherein said diagnostic device is an angiographic injector system.

40 11. A medical information management and medical device control system comprising a World Wide Web site comprising:

- 45 a) one or more communication interfaces containing software for:  
(1) receiving and translating medical information and medical device operating instructions form a plurality of diverse medical devices which allows said plurality of diverse medical devices to communicate with one another and to communicate with a receiving appliance;  
(2) transmitting said medical information and said medical device operating instructions received from said plurality of diverse medical devices to said receiving appliance;

50

(3) receiving and translating said medical information and said medical device operating instructions from a plurality of diverse medical devices and routing said medical information and said medical device operating instructions to said databases for processing and storage;

(4) receiving and translating said medical information and said medical device operating instructions from a third party and routing said medical information and said medical device operating instructions to said databases for processing and storage;

(5) receiving requests from an operator of a medical device and routing said request to said databases;

(6) receiving and transmitting said medical information and said medical device operating instructions extracted from said databases in response to said request received from said operator; and

(7) receiving and transmitting said medical information and said medical device operating instructions necessary for the remote command and control of the medical device in response to instructions from said operator;

b) a plurality of user accessible databases containing:

(1) information related to coordinating the operation of multiple, diverse medical devices that are used simultaneously in the treatment or diagnosis of a patient in need thereof;

(2) technical information pertaining to the operation and maintenance of a medical device;

(3) answers to frequently asked questions regarding the operations of the medical device; and

(4) a user profiles database containing a series of sub-databases; and

c) a portal to other World Wide Web sites.

12. The medical information management and medical device control system comprising a World Wide Web Site of claim 11 wherein said user profile sub-databases are selected from the group consisting of: medical device database, and user preferences database.

13. A method of managing medical information and controlling medical devices comprising the steps of:

a) providing a World Wide Web site comprising:

(1) a communication interface;

(2) a plurality of user accessible databases comprising:

- 5            b)     provides for collection of clinical information in a sterile field environment  
wherein the user is within the sterile field;  
c)     provides a connection to the Internet; and  
d)     provides a mechanism to display medical imaging data for the user.
